Abstract
Visual Question Answering (VQA) has been widely explored as a computer vision problem, however enhancing VQA systems with linguistic information is necessary for tackling the complexity of the task. The language understanding part can play a major role especially for questions asking about events or actions expressed via verbs. We hypothesize that if the question focuses on events described by verbs, then the model should be aware of or trained with verb semantics, as expressed via semantic role labels, argument types, and/or frame elements. Unfortunately, no VQA dataset exists that includes verb semantic information. We created a new VQA dataset annotated with verb semantic information called imSituVQA. imSituVQA is built by taking advantage of the imSitu dataset annotations. The imSitu dataset consists of images manually labeled with semantic frame elements, mostly taken from FrameNet.

Keywords: Visual Question Answering, Verb Semantics, FrameNet, Data Augmentation

1. Introduction
The goal of a Visual Question Answering (VQA) system is to answer user questions about an image (Antol et al., 2015b). Neural network based VQA models require large datasets in order to be trained efficiently (Kafle and Kanan, 2017). Currently available datasets approach the task mostly from a visual point of view. The questions are usually about objects, object attributes, object presence, object frequency, spatial reasoning and so on. However we believe the language component should play a major role as well. Exploring currently available VQA datasets, we realized a considerable portion of questions involve a verb other than "to be". We analyzed the VQA dataset (Antol et al., 2015a) since it has been widely used and also includes open-ended free-form questions. As shown in Figure 1, 43% of questions involve a verb other than "to be" in the VQA dataset. In order to compute the distribution of verbs, we used an automatic semantic role labeler. For example, the output labels for the question: "What is the bride wearing on her head?" is: V:wear.01 A0:bride AM-LOC:on R-A1:what. V:verb.0x pattern is used to check whether verb equals 'be' or not. Therefore, we hypothesize that event verbs such as cook or catch, inherently provide semantic information that may help in answering questions about images describing such events.

Semantic information about verbs includes the type of arguments a verb can take and how the arguments participate in the event expressed by a verb, but this information is missing in current VQA systems. A VQA system aware of or trained with such semantic information can narrow down possible responses. For example, the answer to the question "What is the man cooking?", should be constrained to be about food. However, neither do VQA datasets encode, nor has any VQA system taken advantage of this information.

Traditionally in linguistics, semantic information about a verb has been captured via so-called thematic or semantic roles (Martin and Jurafsky, 2009), which may include roles like agent or patient as encoded in a resource such as VerbNet (Kipper et al., 2008). Semantic role labeling has been shown to improve performance in challenging tasks such as dialog systems, machine reading, translation and question answering (Strubell et al., 2018; Shen and Lapata, 2007). However, the difficulty of clearly defining such roles has given rise to other approaches, such as the abstract roles provided by PropBank (Palmer et al., 2005), or the specialized frame elements provided by FrameNet (Fillmore et al., 2003). In FrameNet, verb semantics is described by frames or situations. Frame elements are defined for each frame and correspond to major entities present in the evoked situation. For example, the frame Cooking creation has four core elements, namely Produced food, Ingredients, Heating Instrument, Container.

In order to create a VQA dataset with verb semantic information, we took advantage of the imSitu dataset (Yatskar et al., 2016), developed for situation recognition. The im-
The datatset for question answering on real-world images (DAQUAR) (Malinowski and Fritz, 2014) was the first dataset and benchmark released for the VQA task. The images are taken from NYU-Depth V2 dataset (Silberman and Fergus, 2012). The images are all of indoor scenes. NYU-Depth V2 is annotated with semantic segmentation, meaning every pixel of an image is labeled with an object class (or no object) out of 894 possible classes. DAQUAR includes 1449 images (795 training, 654 test). Question answer pairs are collected in two ways: (1) manually by human annotators with focus on colors, numbers and objects; (2) using predefined templates to generate from the NYU dataset ("How many [object] are in [image id]?") In total, 12,468 question answer pairs were collected (6,794 training, 5,674 test). Unfortunately, DAQUAR is restricted as the answers are among a predefined set of 16 colors and 894 object categories. It also suffers from bias resulting from humans focusing on a few prominent objects such as tables and chairs in the image. Beside accuracy, the authors proposed WUPS in order to measure performance. WUPS is defined based on WUP (Wu and Palmer, 1994). WUP(a, b) measures similarity based on the depth of two words a and b in a taxonomy such as WordNet. WUPS generates a score between 0 and 1. It is typically thresholded by 0.9 indicating whether an answer is correct or not.

Many VQA datasets utilize Microsoft Common Objects in Context (MS-COCO) (Lin et al., 2014) image dataset. The MS-COCO consists of 2.5 M instances of 91 object types for object recognition. The images are taken from complex everyday scenes of common objects in a natural context. The COCO-QA dataset (Ren et al., 2015) is a dataset based
on the MS-COCO dataset. It was one of the first attempts in increasing the scale of the dataset for the VQA task. The <question, answer> pairs are automatically generated from MS-COCO caption annotations. The questions generally fall in four categories: Object, Number, Color and Location. For each image, there is one question with a single word answer. The dataset contains a total of 123,287 samples (72,783 training and 38,948 testing). Performance is assessed via either accuracy or WUPS score. The automatic conversion of captions results in a high repetition rate of the questions. Also since captions are describing the main information of the image, it does not provide detail specific questions.

The VQA dataset (Antol et al., 2015a) is the most widely used dataset for the VQA task. It is mostly because of the free-form and open-ended design of the questions and answers. For open-ended questions, potentially major AI capabilities are needed to answer: fine-grained recognition (e.g., "What kind of food is served?"); object detection (e.g., "How many zebras are there?"); activity recognition (e.g., "Is this man playing tennis?"); knowledgebase reasoning (e.g., "Is this a hybrid car?"); and commonsense reasoning (e.g., "Does this person follow the rules?"). Real images are selected from the MS-COCO dataset. Questions and answers were generated by crowd-sourced workers. For each question image pair, 10 answers were obtained from unique workers. Answers are usually a single word or a short phrase. Almost 38% of the questions are Yes/No, 12% Number and 50% Others. The original VQA dataset has 204,721 images with 614,163 questions, 3 questions per image on average (248,349 training, 121,512 validation, 244,302 testing). The second version of the VQA 2.0 has also been proposed (Goyal et al., 2017). It extends the VQA dataset by balancing Yes/No type of questions. A machine response is evaluated via a VQA specific accuracy measure. An answer is considered correct if it matches the answers of at least three annotators.

The Visual Genome QA (Krishna et al., 2017) is the largest dataset for VQA, (1.7 M question/answer pairs). It includes structured annotations known as scene graphs. These scene graphs specify visual elements, attributes, and relationships between elements. Questions were created by human subjects. Questions start with one of the 7 possible question words (Who, What, Where, When, Why, How, and Which). A major advantage of the Visual Genome QA dataset for VQA is the structured scene annotations. The diversity of the answers is also larger in comparison to VQA. The Visual7W dataset (Zhu et al., 2016) is a subset of the Visual Genome dataset with additional annotations. Objects mentioned in the question were drawn with bounding boxes in the image in order to resolve textual ambiguity and to enable answers of a visual nature. The questions are evaluated in a multiple choice way with 4 candidate answers of which only one is correct. The dataset contains 47,300 images and 327,939 questions.

The Compositional Language and Elementary Visual Reasoning diagnostics dataset (CLEVR) (Johnson et al., 2017) was proposed to alleviate the biased problem of VQA benchmarks. This way it prevents the models from exploiting the situation in order to answer questions without reasoning. It challenges visual reasoning capabilities such as counting, logical reasoning, comparing, and storing information in memory. It is designed so that accessing external knowledge bases and using common sense may not help in order to answer the questions. Images are annotated with ground-truth object positions and attributes (shape, size, color, material). Questions are generated automatically using textual templates (i.e., "How many <Color> <Material> things are there?") from 90 question families. CLEVR has 100K rendered images (simple 3D shapes) and about one million questions of which 853K are unique. The focus of many VQA datasets is on questions that require direct analysis of an image in order to answer. There are many questions that require common sense, or basic factual knowledge to be answered. FVQA (Fact-based VQA) (Wang et al., 2018) was proposed by appending supporting fact information to VQA (<image, question, answer> samples). The supporting fact is represented as a triplet such as <Cat, CapableOf, ClimbingTrees>. 2190 images were sampled from the MS-COCO. Each image is annotated with visual concepts (objects, scenes, and actions) using available resources and classifiers. The knowledge about each visual concept is extracted from structured knowledge bases, such as DBpedia, ConceptNet, and WebChild. Annotators created 5,826 questions in which answering each question requires information from both the image and selected supporting facts.

3. The imSituVQA Dataset

This section briefly describes the imSitu dataset and explains the process of a novel VQA dataset creation (imSituVQA) from the currently available imSitu dataset. The process is composed of two primary steps: (1) Question answer template generation: Question answer templates are generated from imSitu abstract verb definitions. (2) Question answer pair realization: The templates are filled with noun values from the imSitu annotated images.

The imSitu dataset (Yatskar et al., 2016) is tailored to situation recognition and consists of about 125k images. Situation recognition is a problem that involves predicting activities along with actors, objects, substances, and locations and how they fit together. imSitu utilizes linguistic resources such as FrameNet (Fillmore et al., 2003) and WordNet (Miller, 1995) in order to define a comprehensive space of situations. It provides representations helping to understand who (AGENT) did what (ACTIVITY) to whom (PATIENT), where (PLACE), using what (TOOL) and so on. A semantic frame is a conceptual structure describing an event or relation and the participants in it. A sample of images from the imSitu dataset and their annotations can be found in Table 1. Every situation in imSitu is described with one of 504 candidate verbs such as cooking, fixing, falling, opening, attaching and so on. Each verb

3The FrameNet database contains over 1200 semantic frames. A semantic frame is a description of a type of event, relation, or entity and the participants in it.

4WordNet is a lexical database of English. Words are grouped into synsets (sets of synonyms), each expressing a concept. These concepts are connected by means of conceptual-semantic and lexical relations forming WordNet.
Abstract definition from imSitu dataset | Sample Generated Question Templates | Response Frame Element
--- | --- | ---
An AGENT cooks a FOOD in a CONTAINER over a HEATSOURCE using a TOOL in a PLACE. | Who is cooking? | AGENT
What does the AGENT cook with TOOL? | FOOD
What is the AGENT doing? | VERB
What does the AGENT use to cook in CONTAINER? | TOOL
Where does the AGENT cook FOOD in CONTAINER? | PLACE
The AGENT buys GOODS with PAYMENT from the SELLER in a PLACE | Who is buying GOODS? | AGENT
What is the AGENT doing? | VERB
What item does the AGENT buy with PAYMENT? | GOODS
Who does the AGENT buy GOODS from? | SELLER
Where does the AGENT buy GOODS? | PLACE
An AGENT catches a CAUGHTITEM with a TOOL at a PLACE. | Who catches at PLACE? | AGENT
What is the AGENT doing? | VERB
What item does the AGENT catches with TOOL? | CAUGHTITEM
Where does the AGENT catches CAUGHTITEM? | PLACE
The AGENT opens the ITEM with the TOOL at the PLACE. | What does the AGENT use to open ITEM? | TOOL
Who opens ITEM? | AGENT
What item does the AGENT opens? | ITEM
Where does the AGENT opens ITEM with TOOL? | PLACE

Table 2: A subset of Question Answer templates generated for cooking, buying, catching and opening.

imSitu includes 190 unique frame elements, some shared among verbs such as AGENT and TOOL, while some are verb-specific such as PICKED ∈ Sr(picking). Every image is labeled with one of the 504 candidate verbs along with frame elements filled with noun values from WordNet. If an element is not present in the image its value is empty. There are about 250 images per verb and 3.55 roles per verb on average.

3.1 Question answer template generation

The main idea behind question template generation is to ask question about one of the frame elements of a given verb based on its abstract definition. For example a question about cooking can ask about AGENT, FOOD, CONTAINER, HEATSOURCE, TOOL or PLACE. Each frame element requires a relevant question word to be used. Consequently, we mapped every frame element to a question word.

Figure 2: Distribution of questions in templates. (a) covers all questions while (b) includes questions starting with question word “what”.

The only exception is question template “What is the AGENT doing?” that the response frame element is labeled with VERB.
Table 3: A subset of frame elements and the question words they are mapped to.

<table>
<thead>

</tr>
<tr>
<td>What [Frame Element]</td>
<td>VEHICLE, CONTAINER, SKILL, SHAPE, PATH, LIQUID IMITATION, MATERIAL, INSTRUMENT, PHENOMENON, OBSTACLE, EVENT</td>
</tr>
<tr>
<td>What does the [AGENT] use to</td>
<td>CROWN, BRUSH, CONNECTOR, GLUE, WRAPPINGITEM, COMPONENT, LOCK, COVER, DYE, PARACHUTE, ACTION, SEALANT</td>
</tr>
</tbody>
</table>

As shown in the first column of Table 2 in imSitu, each verb is described by an abstract statement including all its frame elements. Therefore, there are 504 abstract definitions in total. An abstract definition defines a natural form of how prepositions and punctuations are used along frame elements. For example, for *cook* the abstract definition is "an AGENT cooks a FOOD in a CONTAINER over a HEATSOURCE using a TOOL in a PLACE". We can easily segment the statement to "[an AGENT] cooks [a FOOD] in a CONTAINER over a HEATSOURCE using a TOOL in a PLACE". Now in order to ask a question about a specific frame element, we hold out its segment. For example if we hold out FOOD then what remains is "[an AGENT] cooks [X] in a CONTAINER over a HEATSOURCE using a TOOL in a PLACE". Then, we should decide which other segments should be included in the question. The only exception is AGENT and it will always be included (with article the AGENT) if not held out as response frame element. Approximately, we considered all possible subsets of segments. For example: "[an AGENT] cooks [X] in a CONTAINER over a HEATSOURCE using a TOOL in a PLACE" are two possible combinations when FOOD is the response frame element. Finally the relevant question word is appended at the beginning of each combination and verb form is modified accordingly. For example: "What does the AGENT cook?" or "What does the AGENT cook in CONTAINER in PLACE?". A subset of question templates and their response frame elements for cooking, buying, catching and opening are shown in Table 2. In total, 6879 templates are generated, with on average 13.65 question-answer templates per verb. Figure 2 shows the distribution of template questions in terms of question words.

Figure 3: Distribution of questions in imSituVQA. (a) covers all questions while (b) includes questions starting with question word “what”

### 3.2. Question answer pair realization

The previous step generates templates for all 504 candidate verbs. As each image in imSitu is annotated with
one verb, the templates of the annotated verb are considered for the image. Templates that include frame elements that are missing or empty in the image annotation are excluded. Then, given each question template and response frame element, the frame elements are filled with the noun values from the annotation. This realization process can be applied to all imSitu images. The final dataset is called imSituVQA. Each sample in imSituVQA is a \(<\text{image}, \text{question}>\) input pair that is labeled with an \(<\text{answer}>\) as output. For example given the image about cooking from Table 1, applying the realization process on "What does the AGENT cook in CONTAINER in PLACE?" results in "What does the boy cook in wok in kitchen?". Realizing the response frame element FOOD results in "meat" as answer. These three items compose a sample \(<\text{image}, \text{question}>; <\text{answer}>\) for VQA task. Table 4 shows VQA samples for cooking, buying, catching and opening. As can be seen, the dataset not only includes the typical question answer pairs but also frame element annotations as well.

If a verb has \(n\) templates, applying an image annotation results in \(n\) real \(<\text{question}, \text{answer}>\) samples of the image. This way, the size of the extracted dataset is the average number of templates times the number of images. This realization process results in 254k train, 88k development and 88k test samples. For the training set, the top 10 most frequent frame element classes among the existing 190 are shown in Table 5. Table 6 also shows the top 10 frequent answers. Because 60% of answers are about PLACE and AGENT, the most frequent answers are usually values from these two frame elements. Figure 5 visualizes the relative frequency of answers and response frame elements in terms of word clouds. The questions are mostly between 4 to 7 words. Figure 4 shows the distribution of imSituVQA questions according to the first question word. As can be seen "Where" is more frequent than "Who" and "What". This derives from PLACE being the most frequent frame element, twice as frequent as AGENT, which is the second.

4. Conclusion

In this paper, we explained how we used the imSitu annotations to build a VQA dataset with verb semantic information. The goal is to enhance the VQA language processing component especially for questions describing events via verbs. Integrating or training VQA models with semantic frame information remains as a research problem to be explored.

One important question is how the VQA model performs on imSituVQA. We did experiment with VQA task on imSituVQA, and we quickly sketch some results here. Since the main goal of this paper was to discuss the process of imSituVQA creation. Using the most frequent answer (prior) in order to answer each question results in 5.65% accuracy. Selecting the most frequent answer per verb results in 22.15% accuracy. Training the CNN-LSTM model proposed in Antol et al., 2015a results in 39.58% accuracy.
